

There are only three of us left – the only three left alive in the world. The great epidemic had wiped out everyone else. It all started in 2023 when a capybara infected with experimental neurovirus had escaped from a secret government research lab in Zimbabwe. The disease it carried caused explosion of human brain – and it was happening in only ten minutes after infection. It took one month to completely destroy African continent. The illness spread quickly around the world, and after six months no human was alive. No **one** except three of us. Me, my sister and Janusz Korwin-Mikke. Somehow, we were immune to disease that had almost eradicated human race. What made us resistant to it? - we do not know, but we suspect that eating a lot of sugar in sugar could have helped us in beating the virus. And here we are – only three of us left – not two, not four but three. What are we going to do? Probably chill out to the end of our lives. I mean – what can happen now, when the humanity has gone? The nature will retake its place, and human race soon will be forgotten. And maybe it is not that bad at all.
